life sciences

Supplemental Figure 1: RR of prestigious authorship across the life sciences per year

Supplemental Methods

Data:

We analyzed the relationship between sex and authorship order, both among R01-supported articles published in cardiovascular journals and R01-supported articles across the life sciences that were recorded in the *PubMed* database. We used two author disambiguation algorithms that allocate authors with their forenames (for sex identification) to articles indexed in *PubMed*. We started with the *Author-ity*¹ algorithm, which includes all papers published before 2009 and has been shown to identify authors with greater than 99 percent accuracy.² We then used the Scopus algorithm for articles published from 2010 up to 2015, which has been found to identify authors across publications with accuracy similar to *Author-ity*.^{2,3}

To determine the probable sex of authors, we wrote a program⁴ in R⁵ that calls the *Genderize* algorithm. *Genderize* associates an individual's forename with the probability of being male and female.⁶ For example, the algorithm designates "Chris" as male with 93% confidence, based on 8,631 verified records in the *Genderize* database. For our analyses, we considered sex determined if the assigned probability met or exceeded a 90% threshold. Comparisons of *Genderize* to other automated algorithms indicate that it provides the most accurate sex assignments.⁷

Finally, we retrieved the 5-year JIFs from the Journal Citation Report (Thomson Reuters, 2015). Note that 5-year JIFs are relatively stable over time – the 2007 scores, the first year available, had a correlation of 0.91 with the 2015 scores in our data. We assigned journals not listed in the Journal Citation Report to the lowest impact strata as the citation report sets a minimum impact threshold for inclusion in the index.

Sensitivity analysis:

Although our main sample for analysis only included articles with at least three authors, we evaluated the robustness of our results in several additional samples, for cardiovascular research (Supplemental Table 2) and across the life sciences (Supplemental Table 3). First, we dropped articles with alphabetical authorship as these articles may signal an equal allocation of credit, with the first and last authorship positions carrying no additional prestige. Second, we only considered articles for which we could designate the gender of all authors to test whether missing information on the sex of some authors might influence our results. Third, we relaxed all sampling restrictions and considered all articles in our relative risk (RR) calculations (including those authored by one or two authors). Across these different samples, our main results remained substantively unchanged.

We also calculated RRs using different confidence thresholds for designating authors' gender. These different thresholds influenced our results by a maximum of two percentage points.

As only a few journals have begun to require the publication of author contributions, we could not assess the contributions of interior authors to the publications across the 3,849 journals included in our analysis. If interior authors tend to be scientific assistants rather than individuals interested in pursuing an academic career and those assistants are disproportionately female, our approach might underestimate women's representation in prestigious authorships. In other words, the higher RR of women earning first authorships would increase, in favor of women. The gap in last authorship, however, appears so large that it seems unlikely that accounting for differential contributions of interior authors would materially impact our results on last authorship.

Finally, we also considered an alternative definition of RR, including last authors in the denominator for the rates of both first and last authorship. This definition does, however, inflate the RR of first authorship in favor of women due to their lower number of last authorships relative to men. Since it would appear unlikely that many senior authors would defer their last authorship for the first author position, our more conservative RR estimate presented in the main manuscript represents the more appropriate calculation, conceptually and empirically.

Confidence intervals and statistical significance:

To assess statistical significance, we calculated 95% confidence intervals for the relative risk of prestigious authorships for women versus men. Specifically, we calculated binomial ratio confidence limits as follows: Given two binomial proportions, p_1 and p_2 , emerging from samples with respective sizes n_1 and n_2 , the formula for the confidence interval for the ratio p_1 / p_2 is:

$$\frac{p_1}{p_2} e^{\pm \Phi^{-1}(\alpha/2) \sqrt{(1-p_1)/(n_1 p_1) + (1-p_2)/(n_2 p_2)}}$$

with Φ^{-1} denoting the normal percent point function. To address the (unlikely) event that either proportion p_1 or p_2 are close to zero in our samples (leading to a division by zero in the above formula), we calculated the Bayes estimators of p_1 and p_2 with F and M denoting, for example, the number of female and male first authorships as follows:

$$p_1 = \frac{F + 0.5}{n_1 + 1} \qquad p_2 = \frac{M + 0.5}{n_2 + 1}$$

Supplemental Figure 1: RR of prestigious authorship across the life sciences per year

Relative risk (RR) of prestigious authorship from 1985 to 2015. The green dashed horizontal line marks the point of equal gender probabilities of prestigious authorship. The red and blue lines represent the RR of first and last authorships, respectively. The grey dashed and dotted lines indicate 95% binomial ratio confidence intervals for the RR of first and last authorship, respectively.
